# AE 03: Duke Forest + data visualization

Gracie Carlaw

```
library(tidyverse)
library(openintro)
```

#### Exercise 1

Suppose you're helping some family friends who are looking to buy a house in Duke Forest. As they browse Zillow listings, they realize some houses have garages and others don't, and they wonder: **Does having a garage make a difference?** 

Luckily, you can help them answer this question with data visualization!

- Make histograms of the prices of houses in Duke Forest based on whether they have a garage.
  - In order to do this, you will first need to create a new variable called garage (with levels "Garage" and "No garage").
  - Below is the code for creating this new variable. Here, we mutate() the duke\_forest data frame to add a new variable called garage which takes the value "Garage" if the text string "Garage" is detected in the parking variable and takes the test string "No garage" if not.

```
duke_forest <- duke_forest %>%
  dplyr::mutate(garage = if_else(str_detect(parking, "Garage"), "Garage", "No garage"))
```

- Then, facet by garage and use different colors for the two facets.
- Choose an appropriate binwidth and decide whether a legend is needed, and turn it off if not.
- Include informative title and axis labels.
- Finally, include a brief (2-3 sentence) narrative comparing the distributions of prices of Duke Forest houses that do and don't have garages. Your narrative should touch on whether having a garage "makes a difference" in terms of the price of the house.

```
duke_forest %>%
  ggplot(aes(x = price, color = garage, fill = garage)) +
  guides(color = FALSE, fill = FALSE) +
  geom_histogram(binwidth = 10000) +
  facet_grid("garage") +
  labs( x = "House Price ($)",
      y = "Number of Houses",
      title = "Duke Forest House Price Compared to Garage Presence")
```

Warning: The `<scale>` argument of `guides()` cannot be `FALSE`. Use "none" instead as of ggplot2 3.3.4.

Presence of a garage does not appear to affect the price of a house. If anything, lack of a garage may lead to a slightly higher house, and the most expensive house does not have a garage, but it is negligible as it is an outlier.

### Important

Now is a good time to render, commit, and push. Make sure that you commit and push all changed documents and your Git pane is completely empty before proceeding.

### Exercise 2

It's expected that within any given market larger houses will be priced higher. It's also expected that the age of the house will have an effect on the price. However in some markets new houses might be more expensive while in others new construction might mean "no character" and hence be less expensive. So your family friends ask: "In Duke Forest, do houses that are bigger and more expensive tend to be newer ones than those that are smaller and cheaper?"

Once again, data visualization skills to the rescue!

- Create a scatter plot to exploring the relationship between price and area, conditioning for year\_built.
- Use geom\_smooth() with the argument se = FALSE to add a smooth curve fit to the data and color the points by year\_built.
- Include informative title, axis, and legend labels.
- Discuss each of the following claims (1-2 sentences per claim). Your discussion should touch on specific things you observe in your plot as evidence for or against the claims.
  - Claim 1: Larger houses are priced higher.
  - Claim 2: Newer houses are priced higher.
  - Claim 3: Bigger and more expensive houses tend to be newer ones than smaller and cheaper ones.
